Chapter 10

The Conformal Model

Excerpted from *Linear and Geometric Algebra* by Alan Macdonald.
June 15, 2018

A Jupyter notebook cm3 for 3D conformal model calculations is available at
the book’s webpage. It is also bundled with the GaAlgebra distribution.

10.1 The Geometric Algebra \( \mathbb{G}^{r,s} \).

An orthonormal basis for the *indefinite* inner product space \( \mathbb{R}^{r,s} \) has \( r \) \( e \)'s with \( e \cdot e = 1 \) and \( s \) \( e \)'s with \( e \cdot e = -1 \). And as in \( \mathbb{R}^n \), \( e_i \cdot e_j = 0 \) for \( i \neq j \).

According to Sylvester’s law of inertia, \( r \) and \( s \) are independent of the orthonormal basis. The special case \( \mathbb{R}^n,0 \) is the \( \mathbb{R}^n \) of earlier chapters.

Axioms I1-I3 in the Definition 4.9 of an inner product space are retained, but I4, “If \( v \neq 0 \), then \( v \cdot v > 0 \)”, is dropped. Set \( r + s = n \). A basis is commonly written \( \{e_1, \ldots, e_n\} \) with \( e_i \cdot e_i = 1 \) for \( i = 1, \ldots, r \) and \( e_i \cdot e_i = -1 \) for \( i = r + 1, \ldots, n \). Then for \( u = \sum_i u_i e_i \) and \( v = \sum_j v_j e_j \) (cf. Eq. (4.8)),

\[
  u \cdot v = u_1 v_1 + \cdots + u_r v_r - u_{r+1} v_{r+1} - \cdots - u_n v_n.
\]

**Exercise 10.1.** Let \( e_+ \) and \( e_- \) be orthogonal vectors in \( \mathbb{R}^{r,s} \) with \( e_+ \cdot e_+ = 1 \) and \( e_- \cdot e_- = -1 \). Show that \( e_+ + e_- \) is null: \( (e_+ + e_-) \cdot (e_+ + e_-) = 0 \).

The existence Theorem 6.1 for \( \mathbb{G}^n \) extends to an existence theorem for the geometric algebra \( \mathbb{G}^{r,s} \). The inner and outer products of blades are defined as in \( \mathbb{G}^n \): \( A \cdot B = \langle AB \rangle_{k-j} \) and \( A \wedge B = \langle AB \rangle_{j+k} \). (The blades of \( \mathbb{G}^{r,s} \) will not be denoted in bold.)

Most properties of \( \mathbb{G}^n \) extend to \( \mathbb{G}^{r,s} \), including the duality relations of Theorem 6.26 and the extended fundamental identity Theorem 6.28. Gram-Schmidt orthogonalization is an exception; it is not available in \( \mathbb{G}^{r,s} \) (Problem 10.6.5).

**Exercise 10.2.** Theorem 7.2a is a test for membership in a subspace of \( \mathbb{R}^n \): \( x \in B \iff x \wedge B = 0 \). (\( B \) on the left is a set; on the right a multivector.) Its proof uses Gram-Schmidt orthogonalization. Prove the test for \( \mathbb{R}^{r,s} \) without it.

---

1Einstein’s relativity theory uses \( \mathbb{R}^{1,3} \). It is called *spacetime* (Cf. Problem 4.3.12).
Chapter 10: The Conformal Model

10.2 The Conformal Model

The geometric algebra $\mathbb{G}^n$ is called the standard model of $\mathbb{R}^n$. The geometric algebra $\mathbb{G}^{n+1,1}$ is called the conformal model of $\mathbb{R}^n$.3

Extend $\mathbb{R}^n$ with two vectors $e_+$ and $e_-$ orthogonal to $\mathbb{R}^n$, with $e_+^2 = e_-^2 = 1$. Then we have $\mathbb{R}^{n+1,1}$, and with it $\mathbb{G}^{n+1,1}$. More useful than $e_\pm$ are the vectors $o = \frac{1}{2} (e_- + e_+)$ and $\infty = e_- - e_+$.

Exercise 10.3. Show and memorize: $o^2 = \infty ^2 = 0$ and $o \cdot \infty = -1$.

Definition 10.1 (Conformal point). The conformal model represents the point $p \in \mathbb{R}^n$ with the vector

$$p = o + p + \frac{1}{2} p^2 \infty \in \mathbb{R}^{n+1,1}. \quad (10.1)$$

The representation is homogeneous: nonzero scalar multiples $ap$ also represent $p$. The vector $p$ in Eq. (10.1) is normalized: the coefficient of $o$ is 1.

Exercise 10.4. a. Show that $p$ is null: $p^2 = p \cdot p = 0$. Important!

b. More generally, show that $p \cdot q = -\frac{1}{2} (p - q)^2$. \hspace{1cm} (10.2)

The squared Euclidean distance $(p - q)^2$ between $p$ and $q$ is linear in $p$ and $q$.

Exercise 10.5. The midplane $\mathcal{M}$ of points $p$ and $q$ in $\mathbb{R}^3$ consists of points equidistant from $p$ and $q$. Show that $r \in \mathcal{M} \iff r \cdot (p - q) = 0$.

Definition (Representations). Let $\mathcal{G}$ be a geometric object in $\mathbb{R}^n$. We say that a blade $G$ in $\mathbb{G}^{n+1,1}$ directly represents $\mathcal{G}$ if $x \in \mathcal{G} \iff x \wedge G = 0$.

By duality, $x \in \mathcal{G} \iff x \cdot G^* = 0$. We say that $G^*$ dually represents $\mathcal{G}$.

Both representations are homogeneous, e.g., for $a \neq 0$, $x \wedge G = 0 \iff x \wedge aG = 0$.

Exercise 10.5 shows that the vector $p - q$ is a dual representation of $\mathcal{M}$.

Equation (10.1) assigns $p = o$ to $p = 0$. So $o$ represents the point at the origin. It is called the origin. Also from Eq. (10.1), $\lim_{|p| \to \infty} p/(\frac{1}{2} p^2) = \infty$ (the vector). Thus the choice of $\infty$ to denote this vector. It is called infinity.

Figure 10.1 shows an imperfect but helpful way to visualize this for $\mathbb{R}^2$. Set a unit sphere on $\mathbb{R}^2$ with its South Pole on the origin $0$. This creates the 1-1 correspondence shown between points $p$ in the plane and points $p$ on the sphere, except the North Pole, labeled $\infty$. The vector $\infty$ represents $\infty$, a single “point at infinity” appended to the plane. As $p$ moves farther from $0$, $p$ gets closer to $\infty$.

Vectors do double duty in $\mathbb{R}^n$ and in $\mathbb{G}^n$, representing both vectors and points (Figure 1.23). Null vectors $p$ do single duty in the conformal model, representing points and only points. Other kinds of vectors represent other kinds of objects. For example, $p - q$ dually represents a midplane (Exercise 10.5).

---

3Much of this chapter was drawn from Geometric Algebra for Computer Science (Revised Edition) by L. Dorst, D. Fontijne, and S. Mann.
10.3 Dual Representations

This section and the next show that the conformal model represents several different kinds of geometric objects. Figure 10.2 lists them. All representations here are in \( \mathbb{R}^3 \), the most important case, although much can be generalized.

**Spheres.** Equation (10.2) immediately gives an equation of the sphere with center \( c \) and radius \( \rho \): \( x \cdot c = -\frac{1}{2} \rho^2 \). This is equivalent to \( x \cdot (c - \frac{1}{2} \rho^2 \infty) = 0 \). Thus the vector
\[
\sigma = c - \frac{1}{2} \rho^2 \infty
\]
is a dual representation of the sphere. More succinctly: \( \sigma \) is a dual sphere.

**Exercise 10.6.** Show that \( \rho \) can be extracted from \( \sigma \):
\[
\rho^2 = \sigma^2.
\]

**Exercise 10.7.** Let \( p = o + \frac{1}{2} p^2 \infty \) represent a point and \( \sigma = c - \frac{1}{2} \rho^2 \infty \) represent a dual sphere. Show that \( 2p \cdot \sigma = \rho^2 - (p - c)^2 \). Thus \( p \) is inside, on, outside the sphere according as \( p \cdot \sigma \) is \( > 0 \), \( = 0 \), \( < 0 \).

Rewrite \( \sigma \) in terms of the center \( c \) of the sphere and a point \( p \) on it:
\[
\sigma = c - \frac{1}{2} \rho^2 \infty = -(p \cdot \infty) c + (p \cdot c) \infty \frac{3}{2} p \cdot (c \wedge \infty).
\]
(10.3)
Step (3) used Problem 9.6.6a. This is a second dual representation of a sphere.

**Planes.** The normal vector \( \pi = n + d \infty \) is a dual representation of the plane orthogonal to a unit vector \( n \) and at distance \( d \) from the origin (in the direction of \( n \)). To see this, compute
\[
x \cdot (n + d \infty) = (o + x + \frac{1}{2} x^2 \infty) \cdot (n + d \infty) = -d + x \cdot n.
\]
Setting this to zero gives the point-normal equation of the plane (Problem 4.1.3b).

**Exercise 10.8.** Extract \( d \) from \( n + d \infty \).

A given point \( p \) in the plane satisfies \( p \cdot (n + d \infty) = 0 \), so \( d = -(p \cdot n)/(p \cdot \infty) \). Substitute this into \( n + d \infty \) and multiply by the scalar\(^4 \) \( -p \cdot \infty \) to obtain a dual representation of the plane through \( p \) and orthogonal to \( n \):
\[
\pi = -(p \cdot \infty) n + (p \cdot n) \infty \frac{3}{2} p \cdot (n \infty).
\]
(10.4)
Step (3) used Problem 9.6.6a. This is a second dual representation of a plane.

**Circles.** We seek a dual representation of the circle with center \( c \), with radius \( \rho \), and is orthogonal to the unit vector \( n \). It is the intersection of the dual sphere \( \sigma = c - \frac{1}{2} \rho^2 \infty \) (Eq. (10.3)) and the dual plane \( \pi = c \cdot (n \infty) \) (Eq. (10.4)). From Theorem 10.3 the circle’s dual representation is the bivector
\[
\psi = \sigma \wedge \pi = (c - \frac{1}{2} \rho^2 \infty) \wedge (c \cdot (n \infty)).
\]
Squaring the circle \( \odot \) gives \( \psi^2 = -\rho^2 \).

**Lines.** Let \( \pi_1 \) and \( \pi_2 \) represent intersecting dual planes. Then the bivector \( \lambda = \pi_1 \wedge \pi_2 \) dually represents their line of intersection (Theorem 10.3 again).

\(^4\)Remember, representations are homogeneous.
10.4 Direct Representations

This section gives direct representations of the geometric objects of the last section. Exercise 10.20 asks you to verify the representations of lines and circles.

**Lines.** A direct representation of the line determined by points \( p \) and \( q \) is \( L = p \land q \land \infty \), i.e., a point \( x \) is on the line if and only if \( x \land (p \land q \land \infty) = 0 \).

Neither \( p \) nor \( q \) can be extracted from \( L \). But the distance between them can:

\[ L^2 = (p - q)^2. \]

If \( x, p, q \) are not collinear, then \( x \land p \land q \land \infty \neq 0 \). This leads to a measure of noncollinearity in numerical work.

Specify a line by a point \( p \) on it and a direction vector \( d \) parallel to it. Then \( p \land d \land \infty \) is a second direct representation of the line. See Section 10.6.

**Circles.** A direct representation of the circle determined by noncollinear points \( p, q, r \) is \( C = p \land q \land r \). Thus a point \( x \) is on the circle if and only if \( x \land (p \land q \land r) = 0 \). Its center is at \( C \infty C \). Its radius \( \rho \) is given by \( \rho^2 = -C^2/(C \land \infty)^2 \). See Problem 10.6.1.

Intuitively, the lines \( p \land q \land \infty \) above are “circles through infinity”.

**Planes.** A direct representation of the plane determined by noncollinear points \( p, q, r \) is \( P = p \land q \land r \land \infty \).

The area \( A \) of the triangle is given by \( A^2 = -P^2/4 \).

Specify a plane by a point \( p \) on it and a direction bivector \( D \) parallel to it. Then \( p \land D \land \infty \) is a second direct representation of the plane. See Problem 10.6.2.

**Spheres.** A direct representation of the sphere determined by noncoplanar points \( p, q, r, s \) is \( S = p \land q \land r \land s \). Its radius \( \rho \) is given by \( \rho^2 = S^2/(S \land \infty)^2 \). Its center is at \( S \infty S \) (unnormalized).

Intuitively, the planes \( p \land q \land r \land \infty \) above are “spheres through infinity”.

**Vectors.** The vectors of vector algebra represent several different kinds of vector-like objects in \( \mathbb{R}^n \): direction vectors (Section 1.1), normal vectors (Problem 4.1.3d), and tangent vectors (Problem 10.7.4). The conformal model represents these different geometric objects differently.

Vector algebra vectors also represent points (Figure 1.23). The conformal model represents them as null vectors (Definition 10.1).

The various objects sometimes transform differently, for example, direction vectors and null vectors under a translation by \( a \) (Problem 10.5.2). Yet the single linear transformation \( T_a \) in the next section correctly translates them all.

Problems 10.4

10.4.1. a. Set \( E = o \land \infty \). Show that \( E^2 = 1 \). *Hint:* Show that \( o \land \infty = e_+ e_- \).

b. Show that \( pE = (o - \frac{1}{2}p^2 \infty) + pE \). This is called a conformal split of \( p \).

c. Expand \( pE = \sum_i p_i e_i E \). Show that the trivectors \( \sigma_i = e_i E \) have the properties of an orthonormal vector basis for \( \mathbb{R}^n \): \( \sigma_i \cdot \sigma_i = 1 \), and for \( i \neq j \), \( \sigma_i \cdot \sigma_j = 0 \). (Hence the use of bold for the \( \sigma_i \).)
10.5 Transformations

Exercise 10.9. a. Let \( p \in \mathbb{R}^n \). Show that \( (\alpha o + p + \gamma \infty)^2 = -2\alpha\gamma + p^2 \). \textit{Hint:} Treat the \( \alpha = 0 \) and \( \alpha \neq 0 \) cases separately.

b. Show that null vectors in \( \mathbb{R}^{n+1,1} \) are of the form \( \beta p \) (\( p \in \mathbb{R}^n \)), \( \gamma \infty \), or 0.

According to Part (b), null vectors, excluding 0, provide a (homogeneous) \textit{algebraic} representation of \( \mathbb{R}^n \equiv \mathbb{R}^n \cup \{ \infty \} \). We will see that \( \infty \) gives sensible results in calculations when thought of as representing \( \infty \), the point at infinity.

A \textit{conformal transformation} of \( \mathbb{R}^n \) preserves scalar angles (not necessarily orientations) between intersecting curves. Examples include several fundamental geometric transformations: rotations, translations, reflections, dilations, inversion. Every conformal transformation is a (not unique) composition of these.

An orthogonal linear transformation \( O \) on \( \mathbb{R}^{n+1,1} \) leaves inner products of vectors invariant (Exercise 9.20a). So \( p \cdot p = 0 \Rightarrow O(p) \cdot O(p) = 0 \), i.e., \( O \) represents a mapping from \( \mathbb{R}^n \) onto \( \mathbb{R}^n \).

The conformal model \( G^{n+1,n} \) represents conformal transformations of \( \mathbb{R}^n \) with orthogonal transformations on \( \mathbb{R}^{n+1,1} \).

We will show this for the five aforementioned conformal transformations. Theorem 10.2f and Problem 10.6.3 together show that the transformations preserve inner products of vectors, and so are indeed orthogonal.

Rotations. In \( G^n \) a rotation of \( p \) by angle \( i\theta \) is represented by \( R_{i\theta}(p) = e^{-i\theta/2} p \, e^{i\theta/2} \) (Section 7.2). In the conformal model it is represented by

\[
R_{i\theta}(p) = e^{-i\theta/2} p \, e^{i\theta/2}.
\]

For \( R_{i\theta} \) rotates \( p \):

\[
e^{-i\theta/2} p \, e^{i\theta/2} = e^{-i\theta/2} (o + p + \frac{1}{2} p^2 \infty) \, e^{i\theta/2} = o + R_{i\theta}(p) + \frac{1}{2} R_{i\theta}(p)^2 \infty.
\]

Exercise 10.10. Verify the just used \( R_{i\theta}(o) = o \) and \( R_{i\theta}(\infty) = \infty \).

Translations. The translation \( p \mapsto p + a \) in \( \mathbb{R}^n \) is represented in the conformal model by

\[
T_a(p) = e^{-a\infty/2} p \, e^{a\infty/2}.
\]

Intuitively, this is a “rotation around infinity”.

Translations in \( \mathbb{R}^n \) are not linear: \( (p + q) + a \neq (p + a) + (q + a) \). The conformal model \textit{linearizes} them with the linear transformations \( T_a \), a boon.

Exercise 10.11. Show that \( e^{\pm a\infty/2} = 1 \pm a \infty/2 \) (exactly).

Exercise 10.12. Show: a. \( T_a(o) = a \). b. \( T_a(\infty) = \infty \). c. \( T_a T_b = T_{a+b} \).

Exercise 10.13. Show: \( T_a(n + d\infty) = n + d\infty + (a \cdot n)\infty \). The normal vector \( n + d\infty \) (Section 10.3) is invariant under \( T_a \) only if \( a \perp n \).
Chapter 10: The Conformal Model

Reflections. Let $\mathbf{n}$ be a vector orthogonal to a hyperplane in the origin of $\mathbb{R}^n$. The reflection of point $\mathbf{p}$ in the hyperplane is represented by $M_n(\mathbf{p}) = -\mathbf{n} \mathbf{p} \mathbf{n}^{-1}$ (Theorem 7.9). The conformal model represents it by

$$M_n(\mathbf{p}) = -\mathbf{n} \mathbf{p} \mathbf{n}^{-1}. \quad (10.5)$$

Exercise 10.14. Prove Eq. (10.5). Hint: First compute $M_n(\mathbf{o})$ and $M_n(\mathbf{\infty})$.

Dilations. The map $\mathbf{p} \mapsto \alpha \mathbf{p}$, $\alpha > 0$, is called a dilation (by $\alpha$). It is represented in the conformal model by

$$D_\alpha(\mathbf{p}) = e^{E \ln \alpha/2} \mathbf{p} e^{-E \ln \alpha/2}. \quad (10.5)$$

To normalize the result, divide by the coefficient of $\mathbf{o}$ (which is $\alpha^{-1}$).

Dilation can be thought of as a “rotation” in the $E$-plane. Recall: $i^2 = -1$ and $e^{i\theta/2} = \cos(\theta/2) + i \sin(\theta/2)$. In contrast, $E^2 = +1$ (Problem 10.4.1a) and $e^{E\beta/2} = \cosh(\beta/2) + E \sinh(\beta/2)$, as a power series expansion reveals.

Inversion. The map $\mathbf{p} \mapsto \mathbf{p}^{-1} = \mathbf{p}/|\mathbf{p}|^2$ is called inversion (in the unit hypersphere). Points inside the sphere are mapped to the outside and vice-versa. Inversion in $\mathbb{R}^n$ is not linear $((\mathbf{p} + \mathbf{q})^{-1} \neq \mathbf{p}^{-1} + \mathbf{q}^{-1})$, but is linearized in the conformal model:

$$I(\mathbf{p}) = -(\mathbf{o} - \frac{1}{2} \mathbf{\infty}) \mathbf{p} (\mathbf{o} - \frac{1}{2} \mathbf{\infty})^{-1}. \quad (10.6)$$

Note: $(\mathbf{o} - \frac{1}{2} \mathbf{\infty})^{-1} = \mathbf{o} - \frac{1}{2} \mathbf{\infty}$. To normalize the result, divide by the coefficient of $\mathbf{o}$ (which is $\mathbf{p}^2$). Inversions reverse orientations.

Exercise 10.15. a. Which points in $\mathbb{R}^n$ are represented by $\frac{1}{2} \mathbf{\infty}$ and $2\mathbf{o}$?
    b. Show that $I(\mathbf{o}) = \frac{1}{2} \mathbf{\infty}$. Intuitively, $\mathbf{0}^{-1} = \mathbf{\infty}$.
    c. Show that $I(\mathbf{\infty}) = 2\mathbf{o}$. Intuitively, $\mathbf{\infty}^{-1} = \mathbf{0}$.
    d. Show that $I(\mathbf{p})$ represents inversion.

Lines, planes, circles, and spheres map to the same under rotations, translations, reflections, and dilations. Inversion is the exception.

Under inversion, lines not through the origin map to circles through the origin and vice versa (Exercise 10.21). Planes not through the origin and spheres through origin are similarly related.

Problems 10.5

10.5.1. Show that inversion $I$ is reflection in the hyperplane normal to $e_+$. 

10.5.2 (Direction vectors). Show that the direction vector $\mathbf{d} \wedge \mathbf{\infty}$ is fixed under $T_a$: $T_a(\mathbf{d} \wedge \mathbf{\infty}) = \mathbf{d} \wedge \mathbf{\infty}$. Direction vectors have a direction $\mathbf{d}$, but not a position. They are like the oriented lengths of Section 1.1 — also called direction vectors there. Compare this to null vectors $\mathbf{p}$ above, where $T_a(\mathbf{p}) \neq \mathbf{p}$ if $\mathbf{a} \neq \mathbf{0}$.

The direct representation of a line, $\mathbf{p} \wedge \mathbf{d} \wedge \mathbf{\infty}$ (Section 10.6), uses a direction vector. The line is determined by a point $\mathbf{p}$ on it and its direction $\mathbf{d} \wedge \mathbf{\infty}$. 
10.6 Covariance

The representations of rotations, translations, and dilations of points in Section 10.5 are of the form $O(p) = VpV^{-1}$. Extend $O$ to all $M \in \mathbb{G}^{n+1,1}$: $O(M) = VMV^{-1}$. Then $O$ is invertible: $VMV^{-1} = N \iff M = V^{-1}NV$.

Theorem 10.2 (Covariance). Transformations of the form $O(M) = VMV^{-1}$ preserve the entire algebraic structure of $\mathbb{G}^{n+1,1}$:

- a. $O(aM) = aO(M)$.
- b. $O(M + N) = O(M) + O(N)$.
- c. $O(M \wedge N) = O(M) \wedge O(N)$.
- d. $B$ a blade $\Rightarrow O(B)$ a blade (same grade).
- e. $O(MN) = O(M)O(N)$.
- f. $O(M \cdot N) = O(M) \cdot O(N)$.

Parts (a)-(c) tell us that $O$ is an outermorphism.

Exercise 10.16. Show that $O$ preserves the inner product of vectors in $\mathbb{R}^{n+1,1}$.

Hint: Recall cyclic reordering from Theorem 6.6.

Proof. a, b. These are obvious.

e. $O(MN) = VMN(V^{-1}) = VMV^{-1} = O(M)O(N)$.

d. Let $B = b_1 \wedge \cdots \wedge b_r$, a blade of grade $r$. Then also $B = c_1 \cdots c_r$, a product of orthogonal vectors. From Part (e), $O(B) = O(c_1) \cdots O(c_r)$. From Exercise 10.16, the $O(c_i)$ are orthogonal, so $O(B)$ is a blade of grade $r$.

Exercise 10.17. Prove Parts (c) and (f) of the theorem. Hint: Consider first blades $M$ and $N$. Use Part (d) and Definitions 6.12 and 6.13.

The proof of this for $\mathbb{G}^n$ (Theorem 6.19a), uses Gram-Schmidt orthogonalization, which is not available in $\mathbb{G}^{r,s}$. Nevertheless, the result remains true in $\mathbb{G}^{r,s}$ (C. Doran and A. Lasenby, Geometric Algebra for Physicists, Cambridge University Press (2007), p. 88; https://en.wikipedia.org/wiki/Geometric_algebra#Blades.2C_grades.2C_and_canonical_basis). Problem 10.6.5 has an example.
As an example, translate by \( a \) the direct line \( L = p \wedge q \wedge \infty \). According to the theorem, the result is \( T_a(L) \). As a check, use covariance directly and \( T_a(\infty) = \infty \): \( T_a(L) = T_a(p) \wedge T_a(q) \wedge \infty \), which represents \( L \) translated.

**Line through \( p \) in direction \( d \).** We show that the trivector \( L = p \wedge d \wedge \infty \) is a direct representation of the line through the point \( p \) and in the direction \( d \).

Start with \( p = o \). We need to solve \( x \wedge (o \wedge d \wedge \infty) = 0 \). The \( o \) and \( \infty \) factors in the parentheses kill the \( o \) and \( \infty \) terms in \( x \), leaving \( x \wedge (o \wedge d \wedge \infty) \). This is zero if and only if \( x \in \text{span}\{o, d, \infty\} \), i.e., if and only if \( x \) is a scalar multiple of \( d \). This establishes the result for \( p = o \).

To finish, translate \( o \wedge d \wedge \infty \) by \( p \) to obtain \( L \) (Step (2) uses Problem 10.5.2):

\[
T_p(o \wedge d \wedge \infty) = T_p(o) \wedge T_p(d \wedge \infty) \quad \overset{?}{=} \quad p \wedge d \wedge \infty.
\]

We have just seen an example of a common strategy:

<table>
<thead>
<tr>
<th>Establish a representation of some well chosen geometric objects.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extend the representation to transformations of the objects using covariance.</td>
</tr>
</tbody>
</table>

**Exercise 10.19 (Dual line).** Let \( C \) represent a circle. Show that the bivector \( \lambda = \infty \cdot C \) dually represents the line orthogonal to \( C \) and through its center.

**Exercise 10.20 (Direct lines and circles).** Justify the direct representations \( L = p \wedge q \wedge \infty \) of lines and \( C = p \wedge q \wedge r \) of circles from Section 10.4. The justifications for planes and spheres are similar, but more complicated.

Representations of reflections and inversions are of the form \( p \mapsto -VpV^{-1} \). Define an extension \( M \mapsto -VMV^{-1} \). It is not covariant (Problem 10.6.3). However, we can use the covariance of the \( VMV^{-1} \) part. Here is an example.

**Reflect a line in a plane.** The reflection of the point \( p \) in the plane through the origin with normal \( n \) is represented by \( -npn^{-1} \) (Theorem 7.9).

The formula extends to the reflection of the line \( L = o \wedge d \wedge \infty \) in the plane. To see this, first use the covariance of \( M \mapsto +Mn^{-1} \) (Theorem 10.2):

\[
nLn^{-1} = (no^{-1}) \wedge (ndn^{-1}) \wedge (n \infty n^{-1}) = (o) \wedge (ndn^{-1}) \wedge (-\infty).
\]

Negate this: \( -nLn^{-1} = o \wedge (-ndn^{-1}) \wedge \infty \). This represents \( L \) reflected, since \( -ndn^{-1} \) represents \( d \) reflected.

**Angle between lines.** We compute the angle \( \theta \) between intersecting lines. Consider first lines intersecting at the origin: \( L_1 = o \wedge d_1 \wedge \infty, L_2 = o \wedge d_2 \wedge \infty \), with \(|d_1| = |d_2| = 1\). Because of the simple form of \( L_1 \) and \( L_2 \), one can compute

\[
L_1 \cdot L_2 = d_1 \cdot d_2 = \cos \theta.
\]

Now translate the lines to an arbitrary position. By covariance, the left side with the new lines still gives \( \cos \theta \). (Scalars are covariant: \( O(a) = V^{-1}aV = a \).)

**Exercise 10.21.** Show that under inversion lines not through the origin map to circles through the origin and vice versa.
Angle between circles. First note that the condition $|d_1| = |d_2|$ is equivalent to $d_1^2 = d_2^2 = 1$. Consequently, $L_1^2 = L_2^2 = 1$.

Let $C$ be a direct circle determined by $p, q, r$. Application of the results for circles and planes from Section 10.4 gives $C^2 = -\rho^2(C \land \infty)^2 = -\rho^2 P^2 = 4\rho^2 A^2$. Thus $C$ can be normalized to square to 1: divide by $2\rho A$.

Now let $C_1$ and $C_2$ directly represent coplanar circles intersecting at two points, both normalized to $C^2 = 1$. Translate the circles so that an intersection point is at the origin. Now invert with 1. This angle preserving conformal transformation maps the circles to straight lines (by Exercise 10.21), and $C^2 = 1$ to $L^2 = 1$ (since $l(1) = -1$). Thus the angle between the circles is given by the same formula as for the lines: $\cos \theta = C_1 \cdot C_2$.

Translate rotations. $R_{i\theta}(p) = e^{-i\theta/2} p e^{i\theta/2}$ represents a rotation around 0 by angle $i\theta$ (Section 10.5). To rotate around $a$ by angle $i\theta$, translate by $-a$, rotate by $i\theta$ around 0, and translate back by $a$:

$$p \mapsto (T_a \circ R_{i\theta} \circ T_{-a})(p) = e^{-a\infty/2} \left( e^{-i\theta/2} \left( e^{a\infty/2} p e^{-a\infty/2} \right) e^{i\theta/2} \right) e^{a\infty/2}$$

$$= \left( e^{-a\infty/2} e^{-i\theta/2} e^{a\infty/2} \right) p \left( e^{-a\infty/2} e^{i\theta/2} e^{a\infty/2} \right) = T_a(e^{-i\theta/2}) p T_a(e^{i\theta/2}).$$

So $T_a(e^{-i\theta/2})$ is the representative of the rotation about $a$. It is the translation by $a$ of the representative $e^{-i\theta/2}$ of the rotation about 0. Nice!

Notice how easy it was to compose the rotation and translations. Try the composition in $\mathbb{G}^n$, where translation by $a$ is $p \mapsto p + a$. You won’t like it. The problem is that in $\mathbb{G}^n$ translation is additive and rotation is multiplicative. Each is simple, but combining them is not.

Exercise 10.22. a. Show that $T_a(e^{i\theta/2}) = e^{T_a(i\theta)/2}$. Thus the rotation about $a$ can also be written $e^{-T_a(i\theta)/2} p e^{T_a(i\theta)/2}$. Nice again!

b. Show that $T_a(i)$ is a 2-blade with $(T_a(i))^2 = -1$.

Problems 10.6

10.6.1 (Center, radius of a circle). Let $C = p \wedge q \wedge r$ represent a circle.

a. Show that its center is $C \infty C$.

b. Show that its radius $\rho$ is given by $\rho^2 = -C^2/(C \land \infty)^2$.

10.6.2 (Plane through $p$ in direction $D$). Show that $p \wedge D \land \infty$ is a direct representation of the plane through $p$ and parallel to the direction bivector $D \land \infty$. Hint: See “Line through $p$ in direction $d$” above.

10.6.3. a. Define $S(M) = -VMV^{-1}$. Show that $S$ does not preserve the geometric product. Thus Theorem 10.2 does not apply to it.

b. Show that $S$ preserves the inner product of vectors, i.e., $S$ is an orthogonal transformation.

10.6.4. Determine again the “Line through $p$ in direction $d$”, this time without invoking covariance. Hint: Set $q = p + d$. Show that $p \wedge d \land \infty = p \wedge q \land \infty$.

10.6.5. Show that Gram-Schmidt orthogonalization as used in Theorem 6.19 fails for $o \land \infty$. Nevertheless, the theorem is true for this blade: $o \land \infty = e_+ e_-$. 
10.7 Intersections

Geometric objects in $\mathbb{R}^n$ meet in lower dimensional objects, their intersection. Examples: The meet of a line and plane intersecting in a point is that point. The meet of distinct intersecting planes is their line of intersection.

Theorem 10.3 (Representation of intersections). Let $A$ and $B$ be blades in $\mathbb{G}^{n+1,1}$ directly representing geometric objects $\mathcal{A}$ and $\mathcal{B}$ in $\mathbb{R}^n$. Let $J$ be a blade representing $\text{span}(A,B)$. Take duals with respect to it: $A^* = AJ^{-1}$, etc.

Then $A^* \wedge B^*$ is a dual representation of the meet $\mathcal{A} \cap \mathcal{B}$.

Proof. (Gregory Grunberg.) Let $x \in J$. Steps (1) and (5) below use the definition of dual and direct representations (Section 10.2). Step (2) follows from Theorem 6.30a, Step (3) from Theorem 6.26, and Step (4) from Theorem 6.29a:

$$x \in \mathcal{A} \quad \& \quad x \in \mathcal{B} \quad \overset{1}{\Rightarrow} \quad x \cdot A^* = 0 \quad \& \quad x \cdot B^* = 0$$

$$x \cdot (B^* \wedge A^*) = 0 \quad \& \quad x \cdot (A^* \wedge B^*) = 0 \quad \overset{2}{\Rightarrow} \quad x \wedge (B^* \cdot A) = 0 \quad \& \quad x \wedge (A^* \cdot B) = 0$$

$$x \wedge A = 0 \quad \& \quad x \wedge B = 0 \quad \overset{3}{\Rightarrow} \quad x \wedge \text{span}(A,B) = 0$$

$$x \wedge J = 0 \quad \overset{4}{\Rightarrow} \quad x \in \mathcal{A} \quad \& \quad x \in \mathcal{B}.$$  

This chain of implications circles around on itself, so all of its statements are equivalent. In particular, for $x \in J, \ x \in \mathcal{A} \quad \& \quad x \in \mathcal{B} \iff x \cdot (A^* \wedge B^*) = 0.$ □

To apply the theorem we need the blade $J$. It represents the join of the geometric objects $\mathcal{A}$ and $\mathcal{B}$. Examples: The join of distinct intersecting lines is the plane containing them. The join of a line and a point not on it is the plane containing them.

The join of distinct points $p$ and $q$ is a new kind of geometric object for us, a point pair, consisting of just the two points. It has a direct representation $p \wedge q$ (Problem 10.7.3). It can also be thought of as representing the 0-dimensional analog of 1-dimensional circles $(p \wedge q \wedge r)$ and 2-dimensional spheres $(p \wedge q \wedge r \wedge s)$.

Unfortunately, there is no general geometric algebra formula expressing $J$ in terms just of $A$ and $B$. But there are efficient algorithms which compute it.

Example. Let $\sigma$ and $\pi$ be dual representations of a sphere and plane intersecting in a circle. The join of the sphere and plane is $\mathbb{R}^3$, so the circle’s dual representation in $\mathbb{G}^{3+1,1}$ is $\sigma \wedge \pi$.

Example. Let $\pi_1$ and $\pi_2$ be dual representations of distinct intersecting planes in $\mathbb{R}^3$. Their join is $\mathbb{R}^3$, so $\pi_1 \wedge \pi_2$ is the dual representation of their line of intersection.

There is an analog of this example in $\mathbb{R}^3$ vector algebra: the cross product of vectors normal to two planes is a vector along the intersection of the planes.

---

6For the application of the theorem here, we must make sure that $A^* \cap B^* = \{0\}$: $y \in A^* \& y \in B^* \Rightarrow y \cdot A = 0 \quad \& \quad y \cdot B = 0 \Rightarrow y \cdot \text{span}(A,B) = 0 \Rightarrow y \cdot J = 0 \Rightarrow y = 0.$
Exercise 10.23. Let \( \mathbf{n} \) and \( \mathbf{n} + d\infty \) be dual representations of parallel planes.

a. Find a dual representation of their intersection.

b. Show: No \( p \) is in the dual representation, but \( \infty \) is. That is, the intersection of the planes in \( \mathbb{R}^n \) is \( \infty \). Intuitively, this makes sense.

Exercise 10.24. Use Theorem 10.3 to compute the intersection of the line containing the points \(-\mathbf{e}_1\) and \(\mathbf{e}_1\) with the line containing the points \(\mathbf{e}_1 + \mathbf{e}_2\) and \(\mathbf{e}_1 - \mathbf{e}_2\). \(\text{Hint: First determine } J.\)

Fig. 10.2: Representations of geometric objects in the conformal model.

Problems 10.7

10.7.1. Let \( \sigma_1 \) and \( \sigma_2 \) be dual spheres of radius \( \rho \) centered at \( \pm \mathbf{e}_1 \).

a. Compute \( C = \sigma_1 \wedge \sigma_2 \) from Theorem 10.3. If \( \rho > 1 \), then \( C \) is the dual representation of the intersection of the spheres, a circle.

b. Show that \( C^2 = 4(1 - \rho^2) \). Thus the spheres intersect in a circle, a point, or not at all, according as \( C^2 < 0, = 0, > 0 \).

By covariance this test works for all sphere pairs of equal radii.

10.7.2. Refer to the first example following Theorem 10.3. Take \( \sigma = o - \frac{1}{2}\infty \) (unit sphere centered at \( o \)) and \( \pi = \mathbf{e}_3 + d\infty \) (plane parallel to xy plane at distance \( d \) away). Compute \( \psi = \sigma \wedge \pi \). Interpret \( \psi \) for different values of \( d \).

10.7.3. Show that \( p \wedge q \) represents the point pair \( \{ \mathbf{p}, \mathbf{q} \} \). \(\text{Hint: By covariance it is sufficient to show this for two (carefully chosen) points. I used } \mathbb{G}\text{Algebra.}\)

10.7.4 (Tangent vectors). Let \( c - \frac{1}{2}\infty \), with \( c = \pm \mathbf{e}_1 \), dually represent two circles in \( \mathbb{R}^2 \) of radius 1. (In \( \mathbb{R}^2 \) circles are spheres.) The circles intersect at the origin with common tangent vector \( \mathbf{e}_2 \). Find a dual representation of the intersection of the circles. \(\text{Ans. } 2o \wedge \mathbf{e}_1.\) Show that the intersection is the origin.

The dual tangent vector \( 2o \wedge \mathbf{e}_1 \) specifies what is common to the circles: their common point at the origin and their common dual tangent vector \( \mathbf{e}_1 \).
Conformal Model: Final Words

The geometric objects and their representations in this chapter are only a fraction of those available. Pablo Colapinto has compiled two remarkable lists. One lists 25 different kinds of geometric objects representable in the conformal model. The other lists 200 constructions in total for them.

Figure 10.3 shows a small sample of the 200, seven (of nine) ways to construct a dual line. The first item says that a dual line can be constructed as an inner product of $\infty$ and a direct circle (Exercise 10.19). (For $\ell$ see footnote a to Definition 6.12.)

\[ \infty \bigcirc \quad I \quad 5 \quad \bigcirc \quad P \quad s \quad * \quad L \quad i \quad n \quad D \quad r \quad b \quad P \quad a \quad r \quad D \quad r \quad t \quad D \quad r \quad v \quad S \quad h \quad p \quad l \quad F \quad l \quad p \quad F \quad l \quad p \quad P \quad l \quad n \]

Fig. 10.3: Operations that Construct a Dual Line

Compare this richness with vector algebra, where vectors are the only kind of geometric object.

We have two geometric algebras for Euclidean $n$-space: the standard model $\mathbb{G}^n$ and the conformal model $\mathbb{G}^{n+1,1}$. In both, blades represent geometric objects. In the standard model an outer product of three vectors represents an oriented volume. In the conformal model an outer product of three null vectors represents a circle. The semantics are different: oriented volumes are not circles. But the syntax is the same: the same rules of geometric algebra apply to both. Thus we need learn the rules only once to work with both.

It is even better than this. With suitable software it is possible to reap the benefits of the conformal model without knowing the rules.

The software must provide functions to (i) construct geometric objects (e.g., a sphere from a center and radius), (ii) transform geometric objects (e.g., translate them), and (iii) retrieve information about geometric objects (e.g. the center of a sphere or the intersection of two spheres).

A user can then think just in terms of geometric objects and transformations, with the conformal calculations hidden away in a magic “black box”. Various software does this to various degrees, including the GA algebra notebook cm3.

It is natural to couple such software with graphing software. The dimension of the 3D conformal model $\mathbb{G}^{3+1,1}$ is $2^5 = 32$ (Problem 6.1.1). Surprisingly, efficient conformal model based graphics programs are only slightly less efficient than those using traditional methods. One estimate is 10%.

Surveying recent applications of geometric algebra to computer science and engineering shows that

The conformal model is where it is at!
